- Show first 5 or 6 lines of data to help understanding

Objectives

This report looks at the use of solar energy during September 2024 in a domestic property in the southern highlands of Scotland. The property previously used oil for heating and electricity for lighting plus cooking but this was changed in order to reduce running costs and the carbon-footprint of the property. A solar array, battery and ground source heat pump were installed in order to attempt to rely solely on solar generated electricity and supplemented with import from the electricity grid only to compensate for short-falls.

The main aims of this data analysis is to answer the following questions:

1. How effectively does the solar generation cover energy consumption?
2. When specifically does the solar generation fall short and require grid import?
3. Would additional battery storage capacity cover these shortfalls?
4. Does the installation meet the expectations at the time of purchase?

WIP - Analysis, expected conclusions:

- 1) Consumption is covered by solar .. or not? how much? how much grid still needed
- 2) Consumption is linked to temperature and house occupancy
- 3) Solar generation is linked to irradiance .. but how much?
- 4) Any other links such as temperature? .. probably not usage or occupancy though?
- 5) ?? Cannot account for £ cost and different costs at times of day .. battery importing then for example
- 6) ?? Battery timing in and out complicates the analysis?
- 7) Increased battery will smooth out across days? forecast storage/impact .. but can't see the intra-day detail to better analyse
- 8) Solar generation meets the forecasts at purchase .. need original data/estimates!?

Summary of The Data

The data analysed comprises four parts, all daily data, 30 observations, for each day in September 2024:

- Weather: Temperature and solar irradiance readings
- Energy Use: Electricity consumption
- Energy Source: The source of electricity: solar, battery or import from the grid
- *Occupied*: The approximate number of hours the house is occupied each day

All data and supporting files can be found online at Github¹.

Weather

Weather data is sourced from the Balquhiddy Weather Station² and consists of:

- *Temp* - the mean daily temperature in °C and is derived from 6 readings taken at 4 hourly intervals over a 24 hour period
- *Irrdnce* - irradiance, a measure of the solar energy experienced over a specified area, units are W/m² and is used to calculate the theoretical power generated from an array of solar panels³

Energy Use & Source

The distribution of power for the house is managed by a Tesla Powerwall and Controller and an iPhone app is used to monitor this, see Figure 1. All electricity data was downloaded via this app. Electricity is measured in Wh.

Electricity used and where it is sourced from:

- *Home_Total* - total energy used by the house
- *From_Solar* - solar power generated by an array of 36 solar panels
- *From_PWall* - battery storage
- *From_Grid* - the national power grid

Electricity generated by the solar panels and where it is used (the controller intelligently makes the routing decisions):

- *Solar_Total* - total energy generated by the solar panels
- *To_Home* - consumption by the house
- *To_PWall* - for battery storage
- *To_Grid* - export to the national power grid

Initial Data Exploration [?? In Method Section ??]

TO DO: Tidy up table columns display . . . look at Pandoc options etc to change layout for table and whole document? <https://pandoc.org/MANUAL.html#synopsis>

Once the sources of data have been collated and loaded the dataset consists of 30 observations and 12 columns. The first 6 rows are shown below:

```
# Display the first 6 rows of the data
kable(head(energy_df), caption = 'First 6 Rows of the source dataset')
```

Table 1: First 6 Rows of the source dataset

| Date | Home_Total | From_Pwa | From_Solar | From_Grid | Solar_Total | To_Home | To_Pwa | To_Grid | Temp | Irrdnce | Occupied |

```
#head(energy_df)
```

To Do.

- ?? overlay temp, irradiance, solar generation
- ?? Overlay temperture and occupation over house usage
- ?? Overlay irradiance and solar generation

House Demand & Solar Energy Sufficiency

The energy consumption of the house can be compared to the weather and its occupancy and the figure below shows this (NB: the temperature and occupancy values have been scaled to only show the relationships and so no values are displayed). There does not appear to be a strong link between the energy demand and the outside temperature but potentially there is with occupancy. This will be explored further in the next section.

The first bar plot below shows the total energy consumed per day by the house and a breakdown of where this energy is sourced from. It appears that the energy generated by the solar panels only meets a small proportion of the total daily consumption, on average 26%.

```
average_solar_percent <- mean(c(energy_df$From_Solar / energy_df$Home_Total)) * 100
print(paste("Straight percentage:", average_solar_percent))
```

```
## [1] "Straight percentage: 26.0395444324628"
```

However, this is misleading as generated solar energy is often first stored in the battery for later use or exported to the grid if the battery becomes full. The second bar plot shows this more clearly. With solar energy distributed to the home, the battery or exported to the grid on average: 62%, 30% and 8% respectively.

```
solar_home_percent <- mean(c(energy_df$To_Home / energy_df$Solar_Total)) * 100
solar_powerwall_percent <- mean(c(energy_df$To_Pwall / energy_df$Solar_Total)) * 100
solar_grid_percent <- mean(c(energy_df$To_Grid / energy_df$Solar_Total)) * 100
print(paste("To Home:", solar_home_percent, "To Powerwall:", solar_powerwall_percent,
            "To Grid:", solar_grid_percent))
```

```
## [1] "To Home: 62.0971977996547 To Powerwall: 29.9891405679381 To Grid: 7.91530834160956"
```

A good measure of how well the solar generation meets the needs of the house's energy consumption is to simply look at how much usage is catered for without any import from the grid, and this is 80% on average.

```
adjusted_solar_percent <- mean(c((energy_df$Home_Total - energy_df$From_Grid) /
                                energy_df$Home_Total)) * 100
print(paste("Without Grid Imported:", adjusted_solar_percent))
```

```
## [1] "Without Grid Imported: 79.9652308577059"
```

```
plot(energy_df$To_Home ~ energy_df$Date, type = 'l', col = 'red')
lines(energy_df$Date, energy_df$Temp, type = 'l', col = "blue")
lines(energy_df$Date, energy_df$Occupied*20, type = 'h', col = "green")
legend("topright", legend = c("Home", "Temp", "Occupied"),
      col = c("red", "blue", "green"), lty = 1)
```

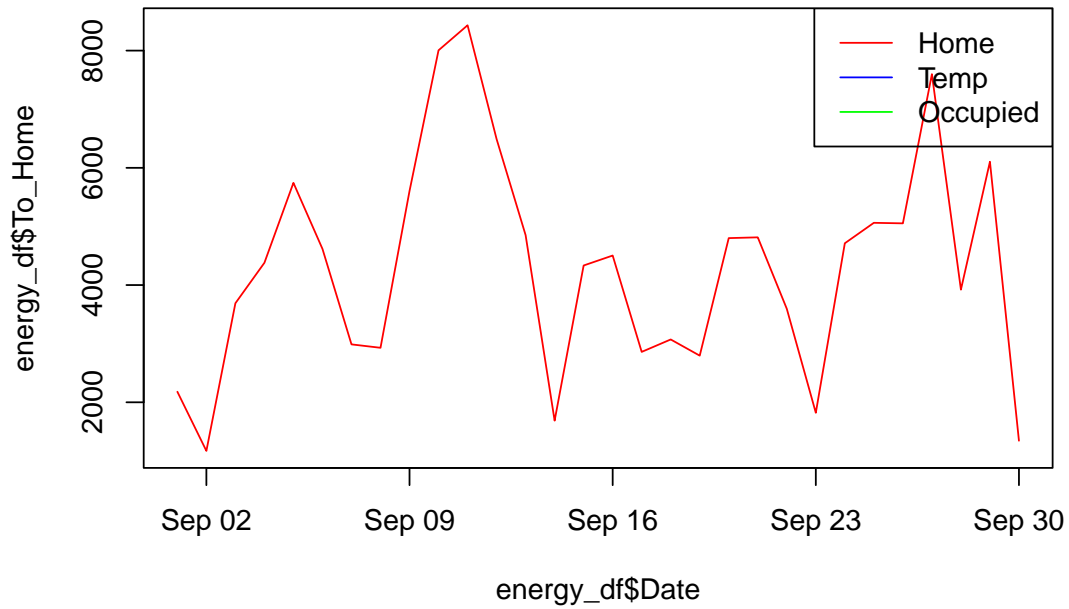

Figure 2: First plot

```
plot(energy_df$Date, energy_df$From_Solar, type = 'l', col = "red")
lines(energy_df$Date, energy_df$Irrdnce/150, type = 'l', col = "blue")
legend("topright", legend = c("Solar", "Irradiance", "xx"),
      col = c("red", "blue", "green"), lty = 1)
```
